PYTHON FOR SUPPLY CHAIN

Session 1 · Mon 16 Nov 2026

Hello, Python

print, variables, types, f-strings, errors

© 2026 Santasila Bryan Kusno. All rights reserved.

Today

1

Colab

`Shift + Enter`

2

print

`show a value`

3

Variables

`a label on a bin`

4

Types

`int  float  str`

5

Maths

`*  round()`

6

f-strings, errors

`f"...{x}"`

© 2026 Santasila Bryan Kusno. All rights reserved.

Why Python for supply chain

Big files

100,000 rows and more

Repeat work

run the weekly steps again

Show your work

every step is written down

Excel stays. Python takes the heavy part.

Colab: text cells and code cells

```
## Variables   (a text cell)
```

```
quantity = 6
print(quantity)
```

```
→ 6
```

Shift + Enter

runs the cell

The result shows right under the cell.

© 2026 Santasila Bryan Kusno. All rights reserved.

Run cells from the top

1
```
quantity = 6
```

2
```
unit_price = 2.55
```

3
```
print(quantity * unit_price)
```

NameError? Run the cells above first.

© 2026 Santasila Bryan Kusno. All rights reserved.

print shows a value

```
print("Hello, supply chain")
print(6)
```

```
→ Hello, supply chain
→ 6
```

`"text"`	`6`
in quotes	no quotes

© 2026 Santasila Bryan Kusno. All rights reserved.

A variable is a label on a bin

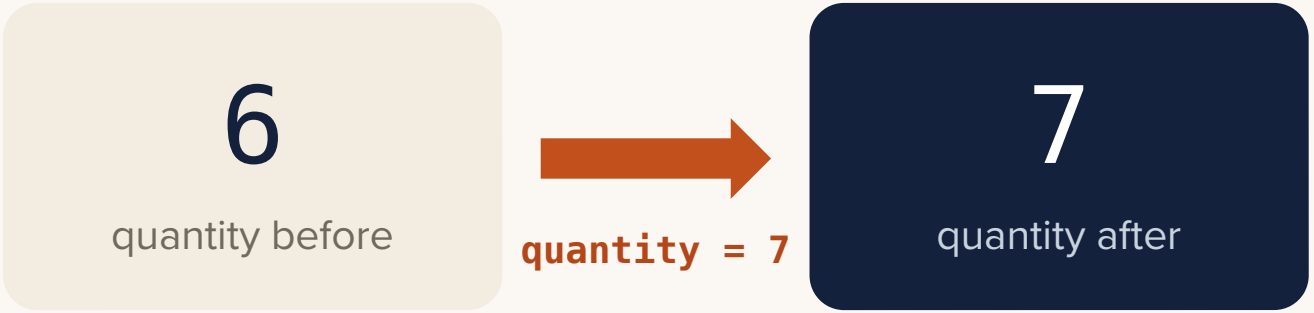

product_name	quantity	unit_price
"WHITE HANGING HEART..."	6	2.55

```
quantity = 6
print(quantity)
```

```
→ 6
```

© 2026 Santasila Bryan Kusno. All rights reserved.

Change it, then run again

Excel updates by itself. A notebook does not. Run the cell again.

© 2026 Santasila Bryan Kusno. All rights reserved.

Three types of value

`int`

`6`

counting boxes

`float`

`2.55`

a price, a weight

`str`

`"LANTERN"`

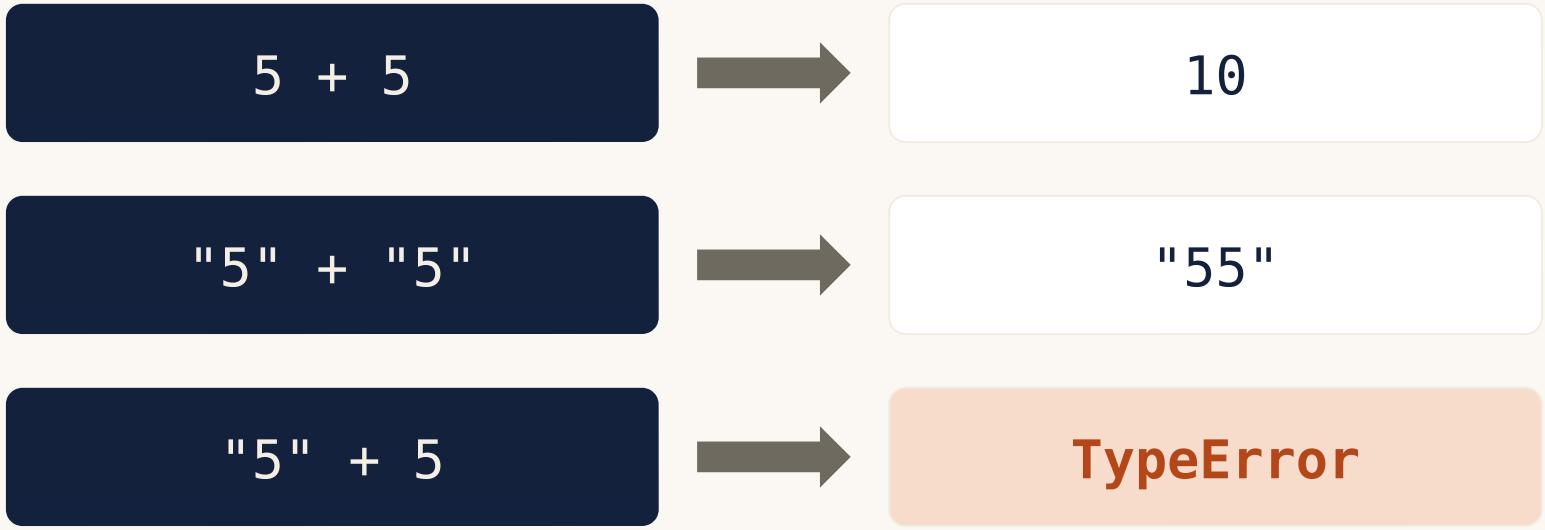

a product name

```
type(2.55)
```

```
→ <class 'float'>
```

© 2026 Santasila Bryan Kusno. All rights reserved.

"5" is text, not a number

Quotes make text.

© 2026 Santasila Bryan Kusno. All rights reserved.

Python as a calculator

+	-	*	/
add	subtract	multiply	divide

```
sales_value = quantity * unit_price
```

Like =B2*C2 in Excel

© 2026 Santasila Bryan Kusno. All rights reserved.

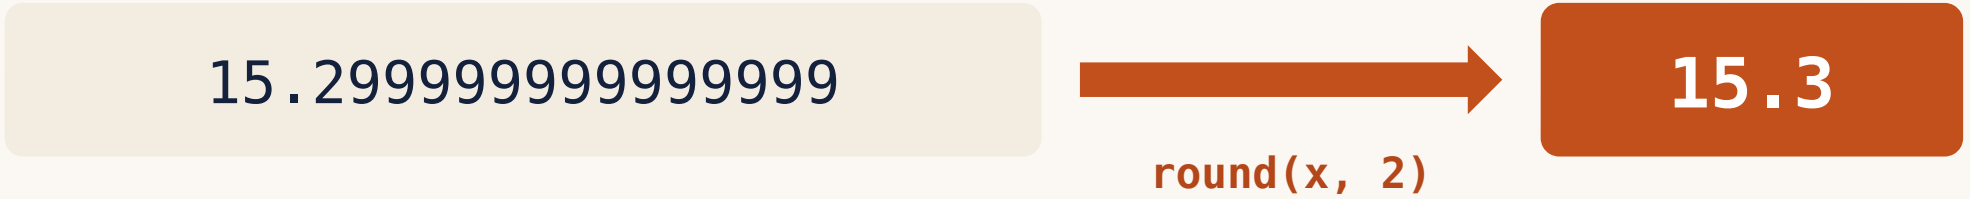

6 × 2.55 is not exactly 15.3

6 × 2.55 = 15.299999999999999

Round money when you show it.

© 2026 Santasila Bryan Kusno. All rights reserved.

round keeps two decimals

```
print(round(sales_value, 2))
```

```
→ 15.3
```

Like ROUND(B2*C2, 2) in Excel

© 2026 Santasila Bryan Kusno. All rights reserved.

An f-string fills in the blanks

```
print(f"We sold {quantity} units for {round(sales_value, 2)} pounds")
```

```
→ We sold 6 units for 15.3 pounds
```

`f`

before the quote

`{quantity}`

the value goes here

No f: the braces print as they are.

© 2026 Santasila Bryan Kusno. All rights reserved.

Read an error from the bottom

```
NameError        Traceback (most recent call last)
<ipython-input-3> in <cell line: 1>()
----> 1 print(quantiy)
```

NameError: name 'quantiy' is not defined

read this line first

© 2026 Santasila Bryan Kusno. All rights reserved.

Three errors you will meet

NameError

unknown name

```
print(quantiy)
```

SyntaxError

a bracket or quote is missing

```
print("hello"
```

TypeError

text and a number mixed

```
"5" + 5
```

Your first toolkit

Code	Does
`print(x)`	show a value
`quantity = 6`	store a value in a name
`type(x)`	int, float or str
`*  /  +  -`	multiply, divide, add, subtract
`round(x, 2)`	keep 2 decimals
`f"...{x}..."`	a sentence with values
